The natural resources that are sustainably extracted from living marine resources.

 x_{np} is the status of the natural products goal

$$x_{np} = \left(\frac{1}{N}\right) \sum_{c=1}^{N} P_c \times w_c$$

$$P_c = H_c \times S_c$$

$$S_c = 1 - \text{average}(E_c + R_c)$$

 S_c is the sustainability of the commodity c

 E_c is ln-transformed harvest intensity: tonnes harvested/km² of coral and/or rocky reef, relative to global max

 R_c risk term based on whether commodity has unsustainable harvest practice, per CITES appendices II & III

 P_c is the status of natural product category c

 H_c is the harvest level for a category relative to its own (buffered) peak reference point

 w_c ratio of max value for product across years, to sum of max values for all products harvested in country

N the number of product categories c harvested
